I. Definition

Project Overview

[Yelp](#) is a social networking site that publishes crowd-sourced reviews about local businesses. About two years ago, Yelp challenged Machine Learning practitioners to build a model that automatically tags restaurants with multiple labels using a dataset of user-submitted photographs. The goal of this project is to develop such a model.

The competition was hosted by [Kaggle](#), a platform where data scientists use their skills to produce the best models for predicting and describing datasets uploaded by companies and users. The various datasets and inputs are accessible via the Yelp Restaurant Photo Classification competition webpage¹. Yelp provides a training dataset (234,842 photographs) and a test dataset (237,152 photographs) for this competition². Each photograph belongs to a business and the task is to predict the business attributes purely from the business photographs. There are 9 different attributes in this problem:

0. good_for_lunch;
1. good_for_dinner;
2. takes_reservations;
3. outdoor_seating;
4. restaurant_is_expensive;
5. has_alcohol;
6. has_table_service;
7. ambience_is_classy;
8. good_for_kids.

and a total of 2,000 (10,000) businesses in the training (test) dataset. Note that this is a multi-instance multi-label classification problem. Each business has multiple photographs and predictions need to be done at the business level. Likewise, multiple labels can be assigned to the same business and hence the classifier needs to account for label dependencies.

Problem Statement

Neural networks have proven to be incredibly efficient at classifying images and often outperform other machine learning algorithms at this task. It comes then as no surprise that deep learning models are used extensively in this project. One now faces two options: i) build and train a deep neural network

¹See <https://www.kaggle.com/c/yelp-restaurant-photo-classification>

²The datasets are quite large. Both the training and test archive files have a size of about 7 GB.

from scratch or ii) use transfer learning³. The properties of the dataset such as its size and nature usually dictate the type of approach to adopt. The Yelp dataset being both large and complex, it would be unrealistic to train a deep neural network model from scratch given this task would require fine expertise and enormous resources. Also, deep neural networks that have been pre-trained on large and diverse dataset like ImageNet⁴ capture universal features in its early layers that are relevant and useful for most computer vision problems. Thus, leveraging such features allows to reach a better accuracy than any method that would rely only on the available data. For those reasons, transfer learning is a better approach for this project

The next step entails the selection of the most relevant pre-trained model for the problem domain. Four state-of-the-art deep learning models whose weights have been pre-trained on the ImageNet database are considered here. For each model, the bottleneck features⁵ are extracted and used as inputs of a very simple classifier. Each classifier is independently trained and their performance is evaluated on an unseen set of features. Based on these results, the best pre-trained deep learning model is selected and used as a fixed feature extractor.

Before feeding the bottleneck features to a classifier, one needs to address the multi-instance aspect of this project. There are essentially two options: i) derive a feature vector for each instance and combine them accordingly to get one feature vector per restaurant or ii) assign to each instance the label of its corresponding restaurant, proceed to classification and average the output probabilities for each label. Both scenarios are investigated in this project.

Finally, a classifier is trained and predictions are made. Two models are considered for the classification task: i) a multi-layer neural network with a final layer containing one node for each label and ii) gradient boosted trees. It is worth noting that a neural network automatically accounts for eventual dependencies among labels because it shares weights for the different label learning tasks. For the other model, label dependencies are handled through classifier chains.

Metrics

The harmonic mean between precision (p) and recall (r), the F_1 score, is used to evaluate the performance of the algorithm:

$$F_1 = 2 \frac{p \cdot r}{p + r} \text{ where } p = \frac{tp}{tp + fp} \text{ and } r = \frac{tp}{tp + fn}$$

In the above formula, tp , fp and fn denote the true positive, false positive and false negative counts, respectively. In a classification task, $p = 1$ for class i means that every item labeled as belonging to class i does indeed belong to class i whereas $r = 1$ for class i means that every item from class i is labeled as belonging to class i . Though, precision says nothing about the number of items from class i that are mislabeled (fn) and recall says nothing about the number of items that are incorrectly labeled as belonging to class i (fp).

Both precision and recall are obviously relevant for a multi-label classification problem and, for this reason, the F_1 score appears as being the best evaluation metric for this project. A good retrieval algorithm will maximize precision and recall simultaneously and, consequently, good performance on both is favored over extremely good performance on one and poor performance on the other. Note that all Kagglers participating to this competition use the F_1 score as evaluation metric. Thus, models can directly be compared and participants easily ranked.

³Machine learning technique where a model trained on one task is re-purposed on a second related task.

⁴Large visual database designed for use in visual object recognition software research.

⁵Last activation map before the fully connected layer.

II. Analysis

Data Exploration

There are 6 different datasets for this competition:

- `train_photos.tgz`
- `test_photos.tgz`
- `train_photo_to_biz_ids.csv`
- `test_photo_to_biz_ids.csv`
- `train.csv`
- `sample_submission.csv`

These files can be found in the data section of the Kaggle competition webpage⁶. Labels of businesses are encoded as integer ranging from 0 to 8. The list of labels for each business is given in `train.csv`. As mentioned previously, each business has multiple photographs. The correspondence between the photo id and the business id can be found in `train_photo_to_biz_ids.csv` (`test_photo_to_biz_ids.csv`) for the training (test) dataset. The photographs for the training (test) dataset are compressed and combined in `train_photos.tgz` (`test_photos.tgz`). All images have `jpg` format and are named after their photo id. There are 234,842 (237,152) photos and 2,000 (10,000) restaurants in the training (test) dataset. Finally, a submission template file (`sample_submission.csv`) is supplied to participants. Results enclosed in this file are used by Kaggle to calculate the model performance and in turn rank participants.

Table 1 features a small sample of the training dataset. It relates business id, labels and photos id. The

	labels	photos id	# photos
business id			
1000	(1, 2, 3, 4, 5, 6, 7)	[438623, 325966, 227692, 407856, 368729, 16319...	54
1001	(0, 1, 6, 8)	[298536, 20346, 8457, 308694, 349310, 407838, ...	9
100	(1, 2, 4, 5, 6, 7)	[338465, 328433, 243861, 361777, 127198, 46652...	84
1006	(1, 2, 4, 5, 6)	[46472, 341947, 396253, 75316, 42330, 244095, ...	22
1010	(0, 6, 8)	[118251, 219940, 27517, 8578, 148347, 433559, ...	11
101	(1, 2, 3, 4, 5, 6)	[13736, 393696, 286907, 86169, 243460, 254663,...	121
1011	(2, 3, 5, 6)	[372371, 116870, 411981, 208597, 127752, 18839...	70
1012	(1, 2, 3, 5, 6)	[287385, 232258, 388225, 151345, 417121, 32754...	37
1014	(1, 2, 4, 5, 6)	[407910, 33911, 269241, 374218, 256236, 296370...	32
1015	(1, 5, 6, 7)	[456770, 44056, 128542, 373344, 87938, 148452,...	145

Table 1: Training dataset. The labels, photo id and number of photos are given for each business id. This table is extracted from the `eda.ipynb` Jupyter notebook.

number of photos available for each business is calculated and reported in the last column of Table 1. One can see that this statistic varies from one entry to the other. The histogram of the number of photos per business for the training dataset is shown in the left panel of Figure 1. Some businesses have very few photos (as low as 2 photos) whereas other have thousands of photos. There is on average 117 photographs per business. The label frequency is shown in the right panel of Figure 1. The least used attributes are `good_for_lunch` (#0), `restaurant_is_expensive` (#4) and `ambience_is_classy` (#7) whereas the most used attributes are `has_alcohol` (#5), `has_table_service` (#6) and `good_for_kids` (#8).

Figure 1: Training dataset statistics. Left: histogram of the number of photos per business. Right: bar plot of the label frequency. These figures are extracted from the `eda.ipynb` Jupyter notebook.

Exploratory Visualization

Figure 2 shows 24 randomly chosen photos that has been tagged as `good_for_kids` (#8). One can see that these photos provide rich local business information. Some photos capture the ambiance/decor of a place whereas other exhibit the food and drinks that are served. Teaching a computer to understand the context of these photos is clearly not an easy task. Objects can easily be misinterpreted and

Figure 2: Photos of the training dataset. Each business has been tagged as `good_for_kids` (#8).

subsequently wrongly classified. For example, condiment bottles that are seen on photo #15160 (1st row and 3rd column) could easily be interpreted as alcohol bottles by a model. Also, it is worth noting that labels are annotated by Yelp users and hence are subjective. To illustrate, some people think that Japanese cuisine is appropriate for kids while other might not. It follows that a restaurant that serves sushis, for instance, will likely not be labeled as `good_for_kids` (#8) by every Yelp users who have eaten there and submitted photographs.
